1. a) 1. Find the node with the assumed name 2. The algorithm:
2. Swap the node we found and the last node
 3. Delete the node we found
 4. Bubble down the swapped node
- The worst case run time is: $O(n) + O(\log n)$

Step 1: $O(n)$ Step 2: $O(1)$ Step 3: $O(1)$ Step 4: $O(\log n)$ The time complexity of the worst case is $O(n)$

- b) 1. Find the node with the assumed priority

2. Swap the node we found with the last node

3. Delete the node we found

4. Bubble down the swapped node

The worst case run time is: $O(\log n) + O(\log n)$ Step 1: $O(\log n)$ Step 2: $O(1)$ Step 3: $O(1)$ Step 4: $O(\log n)$ The time complexity of the worst case is $O(\log n)$

- c) 1. Swap the node at the index and the last node

2. Delete the node at the index

3. Bubble down the swapped node

Step 1: $O(1)$ Step 2: $O(1)$ Step 3: $O(\log n)$ The worst case run time is: $O(\log n)$ The time complexity of the worst case is $O(\log n)$ which is still belongs to $O(n)$

2. The algorithm:

 $i = 0$ while $i \neq n-1$ if $i == \text{keyValue}(A[i])$ $i++$

else

swap($A[i]$, $A[\text{keyValue}(A[i])]$)

endif

endwhile

Note: The function keyValue return the key value of an element in array A.So this algorithm basically loop from 1 to $n-1$

and in the loop, check if the current element

index in the array equal to its value. If it

is, the counter of the loop plus 1. Otherwise,

swap the current element with the element at the

index is the key value of the current element.

For example when $i=0$ and $A[5] = \{3, 1, 2, 0\}$,then we do swap $\Rightarrow A[5] = \{0, 1, 2, 3, 4\}$.Then, $A[5] = \{0, 1, 2, 3, 4\}$, since $i == \text{keyValue}(A[i])$ $i++$; We keep doing this until the loop is done

3. The algorithm:

1. convert the array to binary (32 bits) enough to

2. create a loop from 0 to 31, counter is "bitIndex"

3. we put every elements which "bit index" to left of

the array. And for those are 1, put them to right of

4. Keep the k^{th} smallest number, delete rest of the array

5. Convert them back.

Step 1: $O(n)$ Step 2+3: $32O(n)$ Step 4: $O(n)$ Step 5: $O(n)$ The run time will be $O(n)$.

This is kind like a binary radix sort

4. a) $n-1$

We compare the first coin with the second coin. If weight of first ^{is not equal to the} weight of second then we know the light one is counterfeit, and the heavy one is genuine. If ~~they~~ their weight is the same we just place the 2nd on a side and keep doing this experiment ~~with~~ ~~the~~ found with other coin, until we found which ~~are~~ are genuine and which are counterfeit. Then we pick a genuine coin and a counterfeit coin, make them a pair, we call this base pair. Then we grab 2 unknown coin and compare them with the base pair. If ~~the~~ unknown pair is lighter, than they all counterfeit, if is heavier, than they all genuine, otherwise we need to weigh the pair and check which is genuine, which is counterfeit.

So for the worst case:

1. We found our base case at last

2. For each unknown pair, 1 genuine 1 counterfeit.

They both ~~are~~ $\geq n-1$.

b) if $\text{compareWeight}(C1; C23) \neq$ "both weight same"

if $\text{compareWeight}(C1, C2; C3, C43) ==$ "first weight more"

if $\text{compareWeight}(C1; C33) ==$ "first weight more"

add C1 to AC1

else

add C2 to AC1

else if $\text{compareWeight}(C1, C2; C3, C43) ==$ "second weight more"

~~add C3 & C4 to AC1~~

if $\text{compareWeight}(C1; C33) ==$ "second weight more"

add C2 to AC1

else

if $\text{compareWeight}(C1; C33) ==$ "first weight more"

add C1 & C4 to AC1

else

add C2 & C3 to AC1

else if $C1 = C2$

if $\text{compareWeight}(C3; C43) ==$ "first weight more"

add C3 to AC1

if $\text{compareWeight}(C1; C33) ==$ "both weight same"

add C1 & C2 to AC1

else if $\text{compareWeight}(C3; C43) ==$ "second weight more"

add C4 to AC1

if $\text{compareWeight}(C1; C43) ==$ "both weight same"

add C1 & C2 to AC1

else

if $\text{compareWeight}(C1; C33) ==$ "first weight more"

add C1 & C2 to AC1

else

add C3 & C4 to AC1

return AC1

So the ~~worst case for~~ this algorithm is 3

which is $4-1=3$

$n-1=3$ which is exactly match part c

4.c) L = "first weight more"
 R = "second weight more"
 M = "both weight the same"

$O(n)$ {
 $i = 2$
 while ($i \leq n+1$)
 switch (compareWeight($C[i]$; $C[i+1]$))
 case L
 add $C[i]$ to AC
 break;
 case R
 add $C[i]$ to AC ; add $C[i+1]$ to AC
 break;
 case M // default
 add $C[i]$ to BC
 endswitch
 $i++$
 endwhile
 $O(1)$ { basePair = $C[i] + C[i+1]$
 while ($i+2 \leq n$)
 switch (compareWeight(basePair; $C[i+1], C[i+2]$))
 case R
 add $C[i+1]$ & $C[i+2]$ to AC
 case M
 if (compareWeight($EA[i]$; $C[i+1]$) \neq L)
 add $C[i+2]$ to AC
 else
 add $C[i+1]$ to AC
 endif; endswitch
 ~~endswitch~~ $i++$
 endwhile
 $i++$
 if ($i == n$)
 if (compareWeight($EA[0]$; $C[i]$) $==$ M)
 add $C[i]$ to AC
 endif
 endif
 return AC

so runtime when
 worst case is: $O(n)$
 which
 match part c)

5.a) ~~return~~ Algorithm: return $AC[0]$

Basically this algorithm will just return first element in the array. Since the array has the size of n and there are at least $\lceil \frac{n}{2} \rceil + 1$ x in that array, also it's like a uniform distribution, but with the probability choose dominant is $\frac{\frac{n}{2} + 1}{n}$ which can be rewrite as $\frac{1}{2} + \frac{1}{n}$ which is larger than $\frac{1}{2}$. ($\frac{1}{2} + \frac{1}{n} > \frac{1}{2}$). Therefore the probability is at least $\frac{1}{2}$, and running time is $O(1)$, since return $AC[0]$ is $O(1)$.

b) Algorithm:

1. Convert the array to binary (32 bits) enough
2. Create a loop from 0 to 31, counter is "bitIndex"
3. We put every elements with "bit index" is 0 to left the array. And 1 to the right of the array.

~~4. Convert binary back to dec~~

4. Convert binary back to dec

5. Return the $AC[0]$

Step 1: $O(n)$

Step 2+3: $32 \cdot O(n)$

Step 4: $O(n)$

Step 5: $O(n)$

This is like a binary radix sort

2. The run time will be $O(n)$.

And since there are at least $\lceil \frac{n}{2} \rceil + 1$ terms of dominant, after the array get sorted, the median must be the dominant x , since the worst case is either dominants are the first half of the last half, but either these case, the median is still the dominant.

Therefore the algorithm always returns the correct answer and has expected-case running time $O(n)$

(a) Median of Medians Algorithm: return A[0]
 Basically this algorithm will select the first element in the array since the array has the size of n and there are at least $\lceil n/2 \rceil + 1$ x in that array, also it is a uniform distribution, but with the probability of $\frac{1}{n}$ which can be removed as $\frac{1}{2} + \frac{1}{n}$ which is larger than $\frac{1}{2}$. Therefore the probability $(\frac{1}{2} + \frac{1}{n}) > \frac{1}{2}$.
 is at least $\frac{1}{2}$, and running time is $O(n)$.
 since return A[0] is $O(1)$.
 (b) Algorithm:
 1. (convert the array to binary (32 bits) array)
 2. create a loop from 0 to 31, convert it to "decimal",
 3. We only count elements with bit value as 0 as left of the array. And 1 to the right of the array.
 4. (convert binary back to decimal)
 5. return the A[31-2]
 Step 1: $O(n)$
 Step 2: $O(32 \times n)$
 Step 3: $O(n)$
 Step 4: $O(n)$
 Step 5: $O(n)$
 The running time will be $O(n)$.
 And since there are at least $\lceil n/2 \rceil + 1$ terms of dominant after the array get sorted, the median must be the dominant x , since the worst case is either dominant on the first half of the last half, but either those cases, the median is still the dominant.
 Therefore the algorithm always returns the correct answer, and has expected time running time $O(n)$.

(a) Median of Medians Algorithm: return A[0]
 Basically this algorithm will select the first element in the array since the array has the size of n and there are at least $\lceil n/2 \rceil + 1$ x in that array, also it is a uniform distribution, but with the probability of $\frac{1}{n}$ which can be removed as $\frac{1}{2} + \frac{1}{n}$ which is larger than $\frac{1}{2}$. Therefore the probability $(\frac{1}{2} + \frac{1}{n}) > \frac{1}{2}$.
